Cytomegalovirus (CMV) is a ubiquitous, highly infectious herpesvirus that causes substantial morbidity and mortality in transplant recipients. The infection occurs at a rate of approximately 40% in bone marrow transplant (BMT) recipients. The virus persists in the body for life, and leads to an increase in the risk of CMV disease in the first 6 months after transplantation and, after that, an increase in mortality. In a randomized trial of prophylaxis with ganciclovir, an antiviral drug that was shown to be effective, CMV disease occurred in 19% of the placebo-treated patients versus 11% of the ganciclovir-treated patients ($p=0.02$). CMV disease was associated with increased transplant-related mortality. The clinical significance of CMV infection in allogeneic and autologous transplant recipients is very similar. The incidence of CMV disease is greater in allogeneic than in autologous recipients. There is no effective antiviral therapy to prevent or treat CMV disease. Current strategies to prevent CMV disease include allogeneic blood transfusion and, after stem cell transplantation, CMV-specific T cells. However, these strategies are not effective in preventing CMV disease in all allogeneic recipients, and there is no evidence that they are effective in preventing CMV disease in those patients who do develop the virus. Recent studies have confirmed that CMV infection results in activation of the innate immune response. In addition, it has been shown that CMV infection can increase the risk of relapse of acute leukemia. In this application, we hypothesize that CMV infection causes the release of a unique microRNA-like miRNA species, miR-155. We further hypothesize that the levels of miR-155 are increased in transplant recipients and that the levels of miR-155 increase with severity of disease. We will use mouse models to test this hypothesis and to explore the cellular and molecular mechanisms underlying this process. In Specific Aim 1, we will determine whether the levels of miR-155 increase with the severity of CMV disease. In Specific Aim 2, we will determine whether CMV infection increases the production of miR-155 and whether inhibition of miR-155 blocks CMV-induced cytokine production in vitro. In Specific Aim 3, we will use a 4bc0debe42
